Cancer is a leading cause of illness, disability and death in New Mexico. In 2019, an estimated 9,330 new cases of malignant cancer will be diagnosed among New Mexico residents. This report provides information about the burden of cancer in New Mexico for policy makers, public health professionals, health care providers, researchers and others who need timely and accurate information to support a broad spectrum of cancer control activities.

THE NEW MEXICO TUMOR REGISTRY

Cancer is a reportable disease in New Mexico. The New Mexico Department of Health has identified the New Mexico Tumor Registry as its designee for conducting routine public health surveillance for cancer in the state. The New Mexico Tumor Registry is a population-based cancer registry that has served New Mexico since 1966. The Registry collaborates with health care providers and other professionals throughout the state to identify incident cancer cases through routine and systematic review of existing records such as pathology reports, medical records, radiation therapy records, hospital discharge lists, and vital records. For each new cancer case, the Registry documents selected information about each patient (e.g., age at diagnosis, sex, race/ethnicity, and place of residence), tumor characteristics (e.g., primary anatomical site, histological type, and stage of disease at diagnosis), and first course of cancer-directed therapy (e.g., surgery, chemotherapy, radiation therapy, and hormone therapy).

The New Mexico Tumor Registry is a founding member of the National Cancer Institute's Surveillance, Epidemiology and End Results (SEER) Program – a consortium of cancer registries that provide high quality cancer surveillance data for the United States. Cancer surveillance in New Mexico is conducted in accordance with prevailing standards established by the National Cancer Institute, the North American Association of Central Cancer Registries, and the American College of Surgeons.

CONTENTS

The first section of this report presents estimates of the number of new cancer cases that are expected to occur among New Mexico residents during calendar year 2019. Incidence and mortality rates are useful measures for comparing the occurrence of cancer among racial/ethnic groups while accounting for differences in the size and age-structure of each population. Therefore, the second section focuses on average annual, age-adjusted incidence and mortality rates by type of cancer, based on the most recent five-year period for which actual cancer case counts and deaths are currently available.

DATA SOURCES

Information presented in this report was compiled with records from the New Mexico Tumor Registry, the SEER Program, and National Center for Health Statistics. Denominators for incidence and mortality rate calculations were derived from U.S. Census Bureau figures.

Information regarding deaths due to cancer among New Mexico residents was obtained from the National Center for Health Statistics at the Centers for Disease Control and Prevention. Death certificates issued by individual states, including New Mexico, are routinely submitted to the National Center for Health Statistics for the purpose of monitoring trends in mortality rates for the United States.

NEW CASES OF CANCER

Estimated Number of New Cases – Description and Methods

Approximately 9,330 new cancer cases are expected to occur among New Mexico residents during calendar year 2019. These estimates were based on recent years of complete data from the New Mexico Tumor Registry. Specifically, simple linear regression techniques were applied to the annual case counts for calendar years 2012-2016 to estimate the number of cases that would be expected to be observed among New Mexico residents during calendar year 2019.

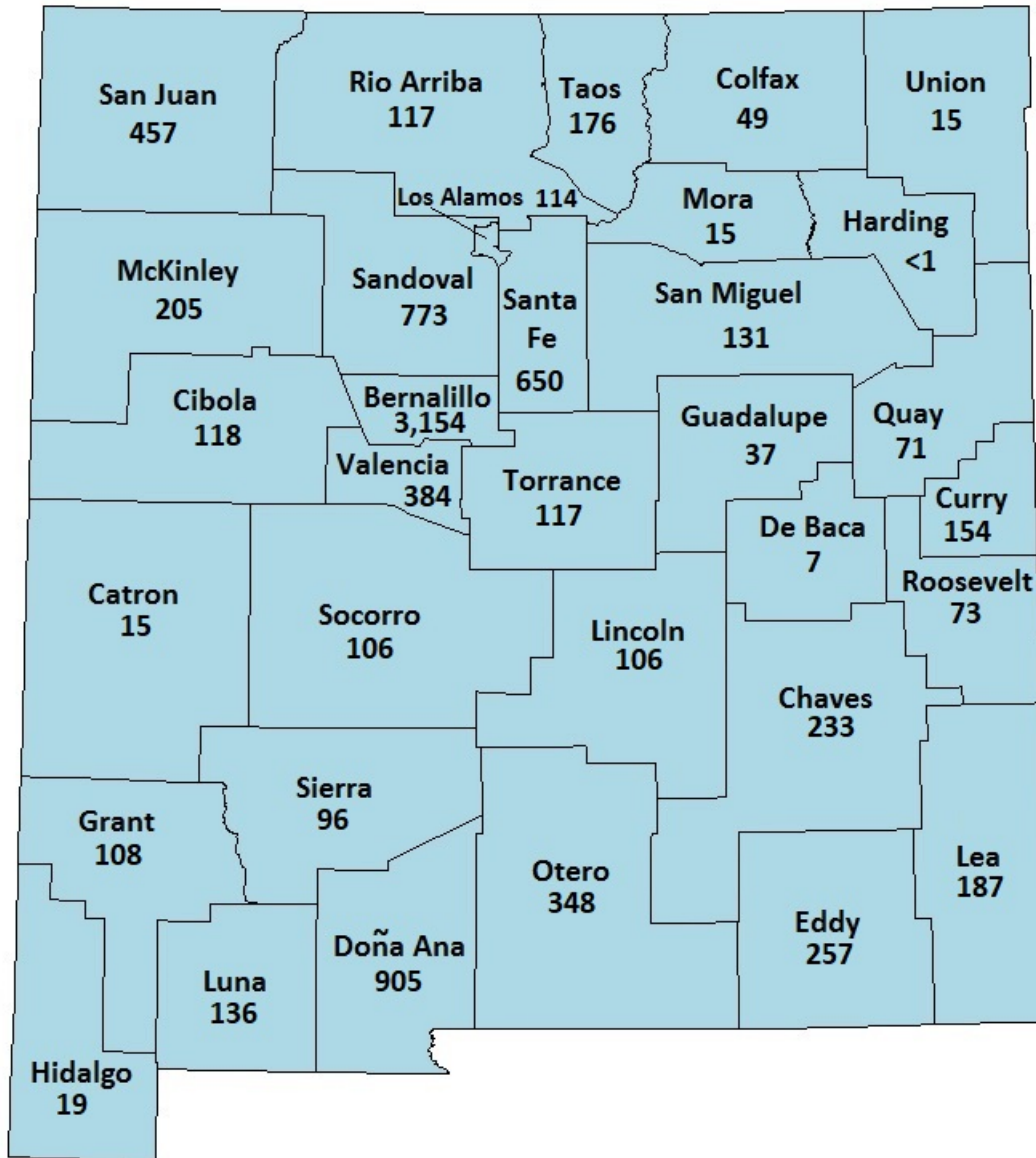

Estimated case counts for several common types of cancer – statewide – are shown in the graph on page 3. Estimated case counts for all malignant cancers (all cancers combined) are shown by county in the map on page 4. Estimated case counts for several common types of cancer by county are shown in the table on page 5.

NEW CASES OF CANCER

Cancer Incidence Rates – Description and Methods

The *incidence rate* is a useful tool for comparing and contrasting the occurrence of cancer among racial/ethnic groups and geographic areas. In the present context, incidence rates measure the “speed” or “velocity” at which members of the target population – New Mexico residents – are diagnosed with cancer during the specified time period.

Cancer can occur at any age, but a majority of cancer cases are diagnosed among older adults. For this reason, comparing cancer rates between two or more populations can be misleading if the underlying age distributions vary among the comparison populations. All incidence rates presented in this report were “age-adjusted” by a common statistical procedure to account for such differences. Specifically, average annual age-adjusted incidence rates were calculated by the direct method and were standardized to the age-distribution of the projected U.S. population for calendar year 2000. Incidence rates were calculated with the National Cancer Institute’s SEER*Stat software system.

Statewide cancer incidence rates for all cancers combined by race/ethnic group and sex are shown in the graph on page 7. Incidence rates for several common types of cancer are shown by race/ethnic group in the tables on page 8 (males) and 9 (females).

CANCER-RELATED DEATHS

Cancer Mortality Rates – Description and Methods

Mortality rates are analogous to the incidence rates that were described in the previous section of this report. In contrast to incidence rates, however, deaths due to a specific cancer serve as the numerator in mortality rates. Thus, mortality rates measure the “speed” or “velocity” at which members of the target population – New Mexico residents – died from cancer during the specified time period.

As with incidence rates, average annual age-adjusted mortality rates were calculated by the direct method and were standardized to the age-distribution of the projected US population for calendar year 2000. The mortality rates were calculated for the time period 2012-2016 since these are the most recent years of data currently available from the National Center for Health Statistics. Mortality rates were also calculated with the National Cancer Institute’s SEER*Stat software system.

Statewide cancer mortality rates for all cancers combined by race/ethnic group and sex are shown in the graph on page 11. Mortality rates for several common types of cancer are shown by race/ethnic group in the tables on page 12 (males) and 13 (females).
